

What is Cryotherapy?

Cryotherapy involves the controlled use of liquid nitrogen to destroy pre-cancerous spots or benign growths. Dr. Al-Dabagh will utilize special equipment to expose the desired spot to liquid nitrogen.

The liquid nitrogen freezes and thaws the abnormal or diseased tissue at a cellular level. He will explain everything in detail before starting.

The cold does sting for a few seconds during therapy. It is normal to develop a blister or scab afterwards. Some lesions, such as warts, may require repeat treatments.
